

ABSTRACT OF THE DISCLOSURE

A flooring nailer includes a main body, and a handle structure mounted on the main body. The handle structure includes a fixing seat and a handle. Thus, the snapping portion of the handle is locked in the locking
5 portion of the fixing seat to form a first locking effect, and the tapered face of the support rack of the fixing seat is rested on the tapered face of the pivot shaft of the handle to form a second locking effect, so that the handle is fixed on the fixing seat rigidly and stably, thereby preventing the handle structure from
detaching from the main body due to the shock or vibration produced during
10 operation of the flooring nailer.
